Pacheco Exercise 3.11

3.11. Finding **prefix sums** is a generalization of global sum. Rather than simply finding the sum of *n* values,

```
x_0 + x_1 + \dots + x_{n-1},
```

the prefix sums are the *n* partial sums

```
x_0, x_0 + x_1, x_0 + x_1 + x_2, \dots, x_0 + x_1 + \dots + x_{n-1}.
```

- **a.** Devise a serial algorithm for computing the *n* prefix sums of an array with *n* elements.
- **b.** Parallelize your serial algorithm for a system with *n* processes, each of which is storing one of the x_i s.
- **c.** Suppose $n = 2^k$ for some positive integer k. Can you devise a serial algorithm and a parallelization of the serial algorithm so that the parallel algorithm requires only k communication phases?
- **d.** MPI provides a collective communication function, MPI_Scan, that can be used to compute prefix sums:

```
int MPI_Scan(
void* sendbuf_p /* in */,
void* recvbuf_p /* out */,
int count /* in */,
MPI_Datatype datatype /* in */,
MPI_Op op /* in */,
MPI_Comm comm /* in */);
```

It operates on arrays with count elements; both sendbuf_p and recvbuf_p should refer to blocks of count elements of type datatype. The op argument is the same as op for MPI_Reduce. Write an MPI program that generates a random array of count elements on each MPI process, finds the prefix sums, and prints the results.
